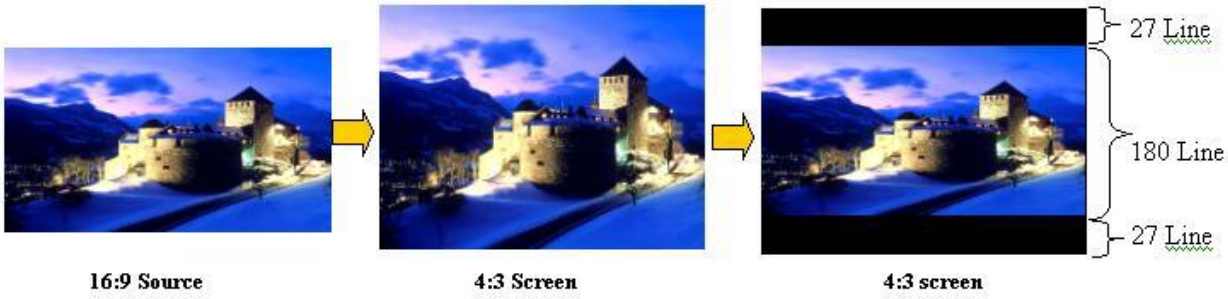
1	1	1	600	9.450		

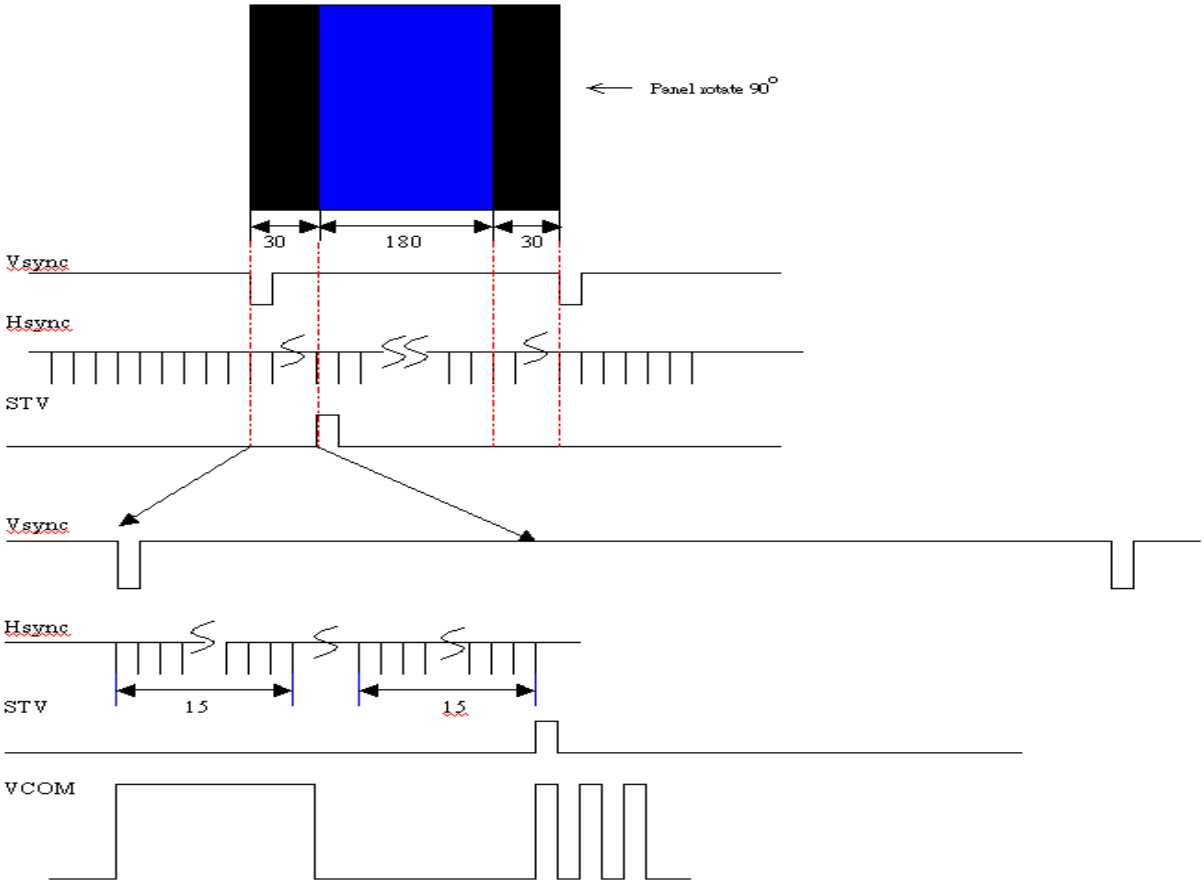
Note 3. NTSC default setting is 594.

PAL default setting is 616.

7.16:9 Wide display

Since the input signal is 240 valid lines. In order to keep 16:9 format, 1/4 lines will be cancelled on the input signal. So the valid lines is 240x0.75=180, Apart from this method, we will also write the black data to TFT. And the black lines are 60 lines where occupied on the up site and bottom site separately.





From above figure,we know that when in black region, We turn on the 15 gate pulses once and then turn on the other 15 gate pulses once. In display region, we show 180 lines normally. Last the black region will be showed and the method is the same as the first 30 lines.

8. DC-DC Converter Circuit

A024CN00 contains one high-power step-up DC-DC converter, and backplane drive circuitry for active matrix TFT LCDs. The output voltage of the main boost converter can be set from VCC to 22V with external resistors. A024CN00 design also include a precision 0.6V reference voltage, fault detection, and logic shutdown.

a .Boost Converter

A024CN00 main boost converter uses a boost PWM architecture to produce a positive regulated voltage, please refer to the below figures to see the block diagram.

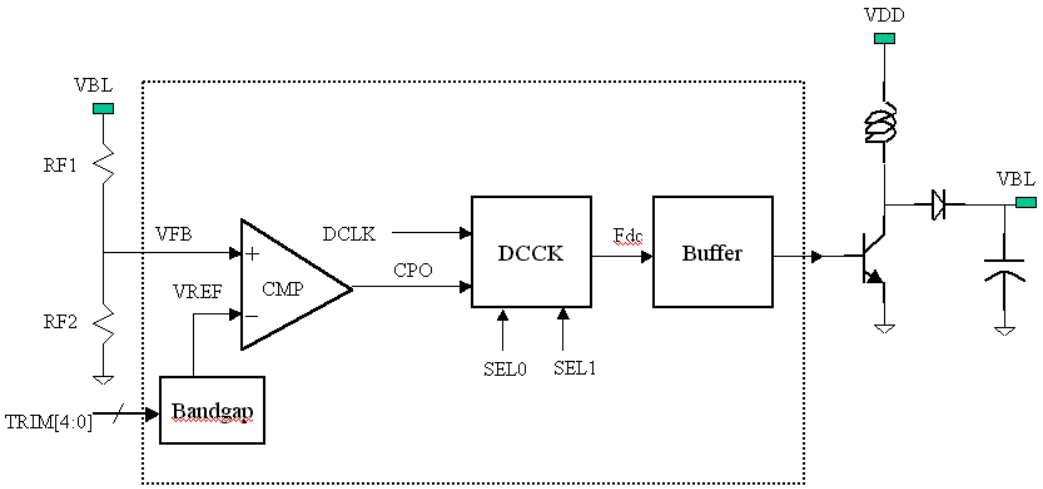


Fig 1 Dc-Dc converter block diagram

In the internal architecture of DC-DC converter. The feedback voltage(VFB) will connect to the triangle waveform comparator, and generates the output signal (CP0) which determines the duty cycle for (Fdc).

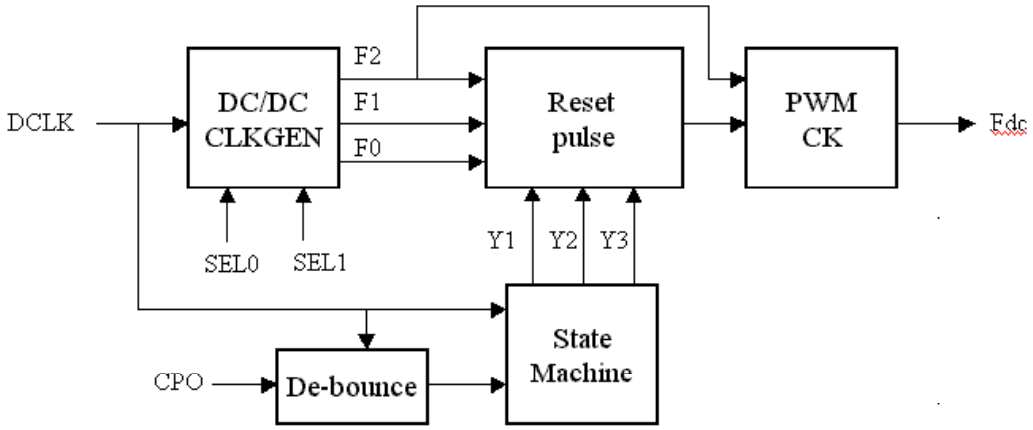

Fig 2 DC CK block diagram

To reduce the noise affect, CP0 will be processed by De-bounce circuit. State-machine will generate the duty cycle by CP0 signal. In order to make sure that VFB can reach default VREF quickly, State-machine's is designed with discrete step by step function (please refer to Fig 3). If CP0 is low, the duty cycle will work from 0% to 83% with the maximum duty ratio to 83%.

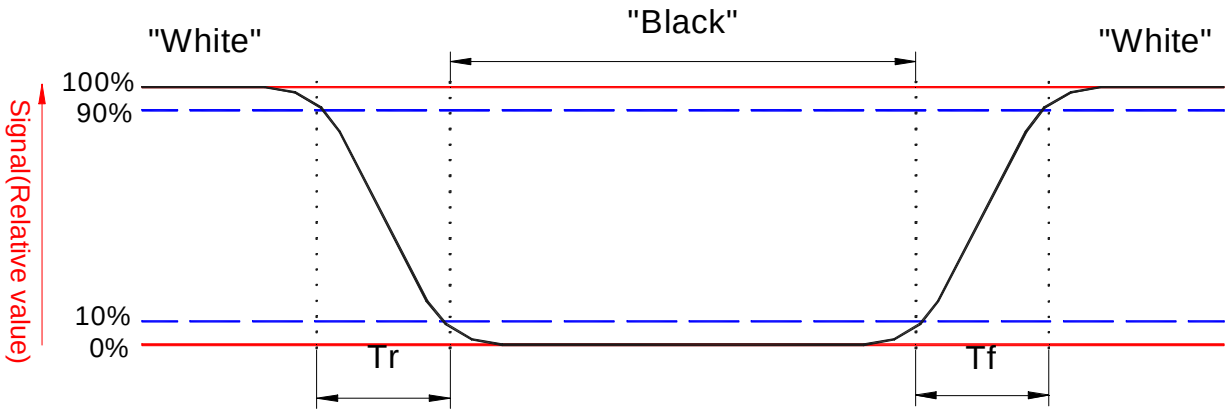
Note 1. Ambient temperature =25℃.
Note 2. To be measured in the dark room.

Note 3.To be measured on the center area of panel with a field angle of 1°by Topcon luminance meter BM-7, after 10 minutes operation.

Note 4. Definition of response time:

The output signals of photo detector are measured when the input signals are changed from “black” to “white”(falling time) and from “white” to “black”(rising time), respectively. The response time is defined as the time interval between the 10% and 90% of amplitudes. Refer to figure as below.



Note 5. Definition of contrast ratio:

Contrast ratio is calculated with the following formula.

$$\text{Contrast ratio (CR)} = \frac{\text{Photo detector output when LCD is at “White” state}}{\text{Photo detector output when LCD is at “Black” state}}$$

Note 6. White $Vi=V_{i50} \mp 1.5V$

Black $Vi=V_{i50} \pm 2.0V$

“±” Means that the analog input signal swings in phase with COM signal.

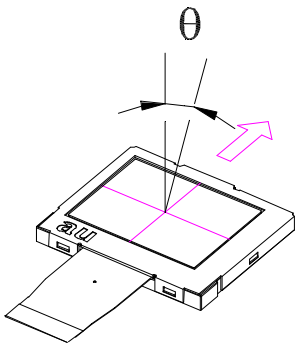
“$\mp$” Means that the analog input signal swings out of phase with COM signal.

V_{i50} : The analog input voltage when transmission is 50%

The 100% transmission is defined as the transmission of LCD panel when all the input terminals of module are electrically opened.

Note 7. Definition of viewing angle:

Refer to figure as below.



Note 8. Measured at the center area of the panel when all the input terminals of LCD panel are electrically opened without APCF (Light enhancement film).
